EXECUTIVE SUMMARY

This report has been prepared by Todoroski Air Sciences for the NSW Environment Protection Authority (NSW EPA) and presents ambient air quality monitoring data recorded in the Lake Macquarie - Wyong region for the month of June 2016. The results indicate that the air quality was generally very good in the Lake Macquarie - Wyong region during June.

The data summary (shown below) indicates that all data recorded in June were below the applicable short term criteria. Further details are provided in the report.

1 INTRODUCTION
This report has been prepared by Todoroski Air Sciences on behalf of the NSW EPA. It provides a summary and analysis of the available ambient air quality and meteorological data collected in the Lake Macquarie - Wyong region during June 2016.

2 PROJECT SCOPE
The following outlines the scope of work for this project.

- Provide a monthly report written in plain English to the NSW EPA summarising and analysing available air quality data and meteorological information.
- The report will be published on the NSW EPA’s website and will assess the available data from monitoring stations operated by the NSW Office of Environment and Heritage (OEH) at Wyong and Wallsend, and by industry at Wyee, Marks Point, Dora Creek, Wakefield and Teralba.
- The aim is to provide a simplified report that is accessible and contains results that would be clearly understood by the general public.

The work is for the period from September 2013 to June 2016.

3 THE PURPOSE OF AMBIENT MONITORING
It is important to note that the data presented in this report are from both NSW EPA and industry monitoring sites. The NSW EPA and the industry sites collect data for different purposes and this needs to be understood when comparing the data to the criteria.

NSW EPA monitoring sites are specifically designed to measure the likely levels of pollutants that the general population in the area would experience (i.e. an underlying population exposure level), whereas industry monitoring sites are specifically designed to measure maximum levels in a particular location that may be affected by a particular industry.

Data from NSW EPA sites can be compared with national air quality standards. Where the levels measured at NSW EPA monitoring sites are above the national standards on a prolonged and consistent basis, this indicates that some investigation of the potential cause of the issue may be warranted to determine whether any action on a regional level would reduce or better manage the pollutant levels. In the case of PM_{10} and PM_{2.5}, it is noted that all data must be published, however days with exceptional events (e.g. bushfires and dust storms) may be excluded for the purpose of assessing compliance with the national standards.

Data from industry monitoring sites can be compared with NSW EPA impact assessment criteria. Where the levels measured at industry monitoring sites are above the applicable impact assessment criteria on a prolonged and consistent basis, this indicates that further investigation is warranted to determine the potential cause and what action is required by industry to reduce or better manage the pollutant.

Whether there is any harmful effect on an individual due to an air pollutant will depend on many additional factors, and not just on the measured level of a pollutant. These factors include the total exposure to the pollutant, individual circumstances (age, health, body mass, levels of pollutants at work), levels of other pollutants in the area, and many other factors.
Where pollutant levels are below the criteria generally, harm would not be expected to occur, but it does not follow that harm automatically occurs when pollutant levels are above the criteria.

The criteria serve to highlight potential issues with the levels of pollutants that may warrant more detailed examination. The criteria may also serve to prioritise action in various areas, for example areas with the highest pollutant levels and highest populations or highest exposure would be expected to receive priority action.

3.1 More about air quality

More information about air quality can be found via the following links:

- The Air Quality Index (AQI) was developed by the NSW EPA as an easily understood means of rating the pollutant level relative to its criteria.

- Aqicn.org provides near real-time AQI values for monitoring locations around the world. It should be noted that the AQI presented on this website is calculated differently to the NSW EPA AQI and is less stringent than those used in Australia, thus a direct comparison may not be valid.
  - http://aqicn.org/map/world/

- The NSW OEH website air quality page provides hourly updates of the AQI and data readings from the NSW EPA monitoring sites, and can provide daily forecasts for Sydney and alerts for elevated levels at Wallsend and Wyong, for example. The web tool also presents near real-time wind and pollutant data readings overlaid on regional maps for the Upper Hunter and Newcastle.

- The Lower Hunter Particle Characterisation Study aims to determine the composition of particulate samples collected at monitoring sites at Beresfield, Newcastle, Stockton and Mayfield, and to identify the potential major sources of fine particulates in Newcastle and the Lower Hunter. Progress reports are published on the OEH website provided below.

- The Air Emissions in My Community web tool presents the estimated emission quantities of various substances and their sources by postcode (and larger) sized areas in an easy to use graphical interface. This is one of the best inventories of emissions that is available, but it is important to appreciate that it cannot include all sources of emissions. It is important to also understand that pollutant emissions are not the same as the pollutant levels that this report presents. Emissions in a given area are one of several important factors that affect pollutant levels in an area, for example the dispersion of the emissions in the atmosphere and how the emissions are released are critical in determining the air quality pollutant levels.

- The NSW Health website provides information on how air pollution affects health and steps for reducing your air pollution and limiting your exposure.
4 AIR QUALITY MONITORING SITES

Figure 4-1 and Table 4-1 summarise the locations and recorded parameters of the monitoring sites in the Lake Macquarie - Wyong region in June 2016.

SO$_2$ - Sulfur dioxide
WS - Wind speed
WD - Wind direction
BOM - Bureau of Meteorology

HVAS - High volume air sampler (which samples for a 24-hour period every 6 days)
5  AIR QUALITY CRITERIA AND STANDARDS

The sections below identify the key pollutants currently being monitored at the Lake Macquarie - Wyong air quality monitoring sites and the applicable air quality criteria and standards.

5.1 Particulate matter

Particulate matter consists of particles of varying size and composition. The total mass of all particles suspended in air is defined as the Total Suspended Particulate matter (TSP). The upper size range for TSP is nominally taken to be 30 micrometres (µm) as in practice particles larger than 30 to 50µm will settle out of the atmosphere too quickly to be regarded as air pollutants.

The TSP is defined further into two sub-components. They are PM$_{10}$ particles, particulate matter with aerodynamic diameters of 10µm or less, and PM$_{2.5}$, particulate matter with aerodynamic diameters of 2.5µm or less.

Table 5-1 summarises the air quality criteria that are relevant to particulate pollutants as outlined in the NSW EPA document Approved Methods for the Modelling and Assessment of Air Pollutants in NSW (NSW DEC, 2005).

<table>
<thead>
<tr>

Source: NSW DEC, 2005

The National Environment Protection Council varied the Ambient Air Quality National Environment Protection Measure (NEPM) on 4 February 2016 (NEPC, 2016) through an amendment that added an annual average standard for PM$_{10}$ concentrations. The updated NEPM removes the allowance for five exceedances of the 24-hour average PM$_{10}$ concentration standard, and requires that all of the data are published, however days with exceptional events (e.g. bushfires and dust storms) may be excluded for the purpose of NEPM compliance assessment.

Table 5-2: NEPM Standards for ambient PM$_{10}$ concentrations

<td>50µg/m$^3$</td>
</tr>
<tr>
<td></td>
<td>Annual</td>
<td>25µg/m$^3$</td>
</tr>
</tbody>
</table>

Source: NEPC, 2016

The NEPM standards apply to the average, or general exposure of a population, rather than to “hot spot” locations such as industry monitoring sites.

5.1.1 PM$_{2.5}$ concentrations

The NSW EPA currently do not have impact assessment criteria for PM$_{2.5}$ concentrations, however standards for PM$_{2.5}$ concentrations are included in the recently updated NEPM (NEPC, 2016) which changed the PM$_{2.5}$ advisory reporting standards to national environment protection standards for PM$_{2.5}$, as shown in Table 5-3.
Table 5-3: NEPM Standards for ambient PM<sub>2.5</sub> concentrations

</tr>
</tbody>
</table>

Source: NEPC, 2016

The NEPM standards apply to the average, or general exposure of a population, rather than to “hot spot” locations such as industry monitoring sites.

5.2 Other air pollutants

Nitrogen dioxide (NO<sub>2</sub>) is reddish-brown in colour (at high concentrations) with a characteristic odour and can irritate the lungs and lower resistance to respiratory infections such as influenza. NO<sub>2</sub> belongs to a family of reactive gases called nitrogen oxides (NO<sub>x</sub>). These gases form when fuel is burned at high temperatures, and mainly originate from motor vehicles, power generators and industrial boilers (USEPA, 2013). NO<sub>3</sub> may also be generated by blasting activities. It is important to note that when formed, NO<sub>2</sub> is generally a small fraction of the total NO<sub>x</sub> generated.

Sulfur dioxide (SO<sub>2</sub>) is a colourless, toxic gas with a pungent and irritating smell. It commonly arises in industrial emissions due to the sulfur content of the fuel. SO<sub>2</sub> can have impacts upon human health and the habitability of the environment for flora and fauna. SO<sub>2</sub> emissions are a precursor to acid rain, which can be an issue in the northern hemisphere; however it is not known to be an issue in NSW.

Ozone (O<sub>3</sub>) has a slight blue colour and is a reactive gas comprised of three oxygen atoms. It is typically found in the upper atmosphere, and forms what is referred to as the ozone layer which filters harmful ultraviolet radiation from the sun, and the near ground level in the troposphere. Tropospheric ozone forms through reactions between nitrogen oxides and volatile organic compounds (VOCs) in the presence of ultraviolet radiation. Tropospheric ozone is the main component of photochemical smog and can impact human health.

Table 5-4 summarises the air quality criteria that are relevant to NO<sub>2</sub>, SO<sub>2</sub> and O<sub>3</sub> as outlined in the NSW EPA document Approved Methods for the Modelling and Assessment of Air Pollutants in NSW (NSW DEC, 2005).

5.3 Summary of applicable criteria for this review

The particulate and gaseous pollutants monitored in the Lake Macquarie – Wyong region have air quality criteria which are averaged over short and long time periods. Annually averaged criteria require a full year of data.
As this report only looks at one month of ambient air quality data, the annual average criteria are not applicable. The SO₂ 10-minute average criterion was not included as 10-minute monitoring data are not available. Therefore the criteria relevant to this assessment are those averaged over the shorter time periods (1-hour and 24-hours).

Table 5-5 summarises the applicable air quality criteria and standards for this review.

6 METEOROLOGICAL MONITORING DATA

Representative wind speed and direction data have been obtained from the Lake Macquarie - Wyong air quality monitoring stations. The data are presented as a series of windroses. For an example of how to read a windrose, refer to Figure A-1 in Appendix A.

Figure 6-1 presents the June 2016 windroses for Wallsend, Dora Creek, Marks Point, Wyee, Norah Head and Wyong.

The figure shows that the meteorological stations recorded winds which varied depending on the local influence of environmental features such as terrain, vegetation and buildings. Overall the stations recorded wind directions predominantly from the southwest to north-northwest.

The Norah Head weather station recorded wind speeds which were generally higher than those recorded at the other stations, particularly from the northern and eastern directions. This is expected as the Norah Head weather station is located in an unsheltered coastal location that would be largely influenced by sea breezes.
The meteorological stations recorded wind directions predominantly from the southwest to north-northwest.
7 AMBIENT AIR QUALITY MONITORING DATA

7.1 Preamble
The monitoring data in this report are presented in raw form as provided to Todoroski Air Sciences by the NSW EPA.

The 24-hour average data presented in this report have been averaged using the 1-hour average readings. Days which contain less than 75% data (less than 18 hours of 1-hour average data) have not been included in this report.

All of the monitoring data provided to Todoroski Air Sciences are presented in this report. The data are shown in the results and Appendices as relevant. 1-hour, 24-hour average and rolling annual average data are presented in a graphical format in Appendix B and 24-hour average data are presented in Appendix C.

7.2 Analysis of Monitoring Data

Table 7-1 presents a summary of the maximum pollutant levels measured during June 2016. The results indicate that pollutant levels recorded in June were below the applicable short term criteria at all monitors at all times.

* Standard for PM$_{2.5}$ concentrations (refer to Section 5.1)
- Not applicable

7.3 PM$_{10}$

Figure 7-1 presents all of the 24-hour average PM$_{10}$ monitoring results recorded in the Lake Macquarie - Wyong region in June 2016.

Relative to the Air Quality Index, as shown by the coloured bands in the figure, PM$_{10}$ levels were very good at all monitors at all times except for the Wallsend monitor which recorded four days with good levels.

All data recorded at the Lake Macquarie - Wyong monitoring sites were less than the PM$_{10}$ criterion level in June.

Figure B-1 to Figure B-2 in Appendix B present the 1-hour average, 24-hour average and rolling annual average PM$_{10}$ data in graphical form for each individual site. There is no criterion that applies to
1-hour average PM$_{10}$ levels and these 1-hour results are not intended to be compared with the PM$_{10}$
criterion. It is a normal occurrence, and it is expected that in the normal environment 1-hour average
PM$_{10}$ levels will fluctuate more significantly than 24-hour average PM$_{10}$ levels.

**Figure B-1 to Figure B-2** show the rolling annual average PM$_{10}$ levels recorded at the Wallsend and
Wyong monitors were 16.6µg/m$^3$ and 15.4µg/m$^3$ respectively at the end of June 2016. The rolling
annual average levels can be compared to the annual average standard of 25µg/m$^3$, however typically
a calendar year of data are used to determine whether the annual average standard has been met.

**7.4 PM$_{2.5}$**

**Figure 7-2** presents all of the 24-hour average PM$_{2.5}$ monitoring data recorded in the Lake Macquarie -
Wyong region in June 2016.

Relative to the Air Quality Index, as shown by the coloured bands in the figure, the data indicate that
recorded PM$_{2.5}$ levels were very good or good at all monitors at all times except for the Wallsend monitor
which recorded one day with fair levels.

All data recorded at the Lake Macquarie - Wyong monitoring sites were below the 24-hour average
PM$_{2.5}$ standard of 25µg/m$^3$ in June 2016.

It should be noted that on 14 and 20 June 2016 the 24-hour average PM$_{2.5}$ levels recorded by the
Wallsend Beta Attenuation Monitor (BAM) were higher than the 24-hour average PM$_{10}$ levels recorded
by the Wallsend Tapered Element Oscillating Microbalance (TEOM) monitor. By definition, PM$_{2.5}$ is a
subcomponent of PM$_{10}$, and so it is not possible for there to be more PM$_{2.5}$ than PM$_{10}$ in the air at any
place at the same time. However, the PM$_{2.5}$ and PM$_{10}$ levels were measured by different regulatory
complaint measurement techniques, and on occasion the measured PM$_{2.5}$ levels may be higher than the
measured PM$_{10}$ levels due to the differing techniques.

**Figure B-3 to Figure B-5** in **Appendix B** present the 1-hour average, 24-hour average and rolling
annual average PM$_{2.5}$ data in graphical form for each individual site. There is no criterion that applies
to 1-hour average PM$_{2.5}$ levels and these 1-hour results are not intended to be compared with the PM$_{2.5}$
standard. It is a normal occurrence, and it is expected that in the normal environment 1-hour average
PM$_{2.5}$ levels will fluctuate more significantly than 24-hour average PM$_{2.5}$ levels.

**Figure B-3 to Figure B-5** show the rolling annual average PM$_{2.5}$ levels recorded at the Wallsend, Wyong
and Wyee monitors were 7.8µg/m$^3$, 5.6µg/m$^3$ and 9.9µg/m$^3$ respectively at the end of June 2016. The
rolling annual average levels can be compared to the annual average standard of 8µg/m$^3$, however
typically a calendar year of data are used to determine whether the annual average standard has been
met.

It should be noted that the Wyee monitor has consistently recorded similar trends and generally higher
PM$_{2.5}$ levels than the Wallsend and Wyong monitors since June 2015. The Wyee PM$_{2.5}$ monitor is
currently under investigation by the operator to determine if the recorded levels are correct, i.e. whether
any abnormally elevated level may be due to the calibration/ performance of the instrument or site factors.
7.5 NO$_2$

Figure 7-3 presents the 1-hour average NO$_2$ monitoring data recorded in the Lake Macquarie - Wyong region in June 2016.

Relative to the Air Quality Index, as shown by the coloured bands in the figure, the data indicate the NO$_2$ levels were very good at all monitors at all times with the exception of the Wyong monitor which recorded an hour of good levels.

All data were below the applicable criterion on all days.

7.6 SO$_2$

Figure 7-4 presents the 1-hour average SO$_2$ monitoring data recorded in the Lake Macquarie - Wyong region in June 2016.

It should be noted that the Wyee monitor did not record data between 11 June 2016 and 17 June 2016 due to an instrument failure.

Relative to the Air Quality Index, as shown by the coloured bands in the figure, the data indicate the SO$_2$ levels were very good at all monitors at all times.

All data were below the applicable criterion on all days.

7.7 O$_3$

Figure 7-5 presents the 1-hour average O$_3$ monitoring data recorded in the Lake Macquarie - Wyong region in June 2016.

Figure 7-6 presents the rolling 4-hour average O$_3$ monitoring data recorded in the Lake Macquarie - Wyong region in June 2016.

Relative to the Air Quality Index, as shown by the coloured bands in the figures, the data indicate the 1-hour average levels of O$_3$ were very good at all times.

The rolling 4-hour average levels were generally very good. The Wallsend and Wyong monitors recorded good levels 1% and 3% of the time respectively.

All data were below the applicable criterion on all days.
The recorded PM$_{10}$ levels were very good at all monitors at all times except for the Wallsend monitor which recorded four days with good levels. All data recorded at the Lake Macquarie - Wyong monitoring sites were less than the 24-hour average criterion of 50µg/m$^3$. 
The recorded PM$_{2.5}$ levels were very good or good at all monitors at all times except for the Wallsend monitor which recorded one day with fair levels. All data recorded at the Lake Macquarie - Wyong monitoring sites were below the 24-hour average PM$_{2.5}$ standard of 25µg/m$^3$. 

Figure 7-2: Lake Macquarie - Wyong 24-hour average PM$_{2.5}$ levels – June 2016
All data recorded at the Lake Macquarie - Wyong monitoring sites were below the 1-hour average NO$_2$ criterion level of 246µg/m$^3$ in June 2016. The measured levels of NO$_2$ were very good at all monitors at all times with the exception of the Wyong monitor which recorded an hour of good levels.
All data recorded at the Lake Macquarie - Wyong monitoring sites were below the 1-hour average SO$_2$ criterion level of 570µg/m$^3$ in June 2016. The measured levels of SO$_2$ were very good at all monitors at all times.
All data recorded at the Lake Macquarie - Wyong monitoring sites were below the 1-hour average $O_3$ criterion level of 214 $\mu$g/m$^3$ in June 2016. Measured 1-hour average levels of $O_3$ were very good at all times.
All data recorded at the Lake Macquarie - Wyong monitoring sites were below the rolling 4-hour average $O_3$ criterion level of 171$\mu g/m^3$ in June 2016. The measured levels were generally very good. The Wallsend and Wyong monitors recorded good levels 1% and 3% of the time respectively.
8 ANALYSIS OF ELEVATED POLLUTANT LEVELS

There were no levels above the applicable criteria in June 2016.
9 CONCLUSIONS

The results indicate that the monitoring stations recorded generally very good air quality during June 2016.

Relative to the Air Quality Index:

- The measured levels of NO$_2$ were very good at all monitors at all times with the exception of the Wyong monitor which recorded an hour of good levels;
- The measured levels of SO$_2$ were very good at all monitors at all times;
- The measured levels of O$_3$ were generally very good. The Wallsend and Wyong monitors recorded good levels 1% and 3% of the time respectively;
- The measured PM$_{2.5}$ levels were very good or good at all monitors at all times except for the Wallsend monitor which recorded one day with fair levels; and,
- The measured PM$_{10}$ levels were very good at all monitors at all times except for the Wallsend monitor which recorded four days with good levels.

All recorded rolling annual average levels were less than the applicable annual (calendar year) standards in June 2016, with the exception of the Wyee monitor which recorded rolling annual average PM$_{2.5}$ levels of 9.9 µg/m$^3$ at the end of June 2016.

It should be noted that the Wyee monitor has consistently recorded similar trends and generally higher PM$_{2.5}$ levels than the Wallsend and Wyong monitors since June 2015. The Wyee PM$_{2.5}$ monitor is currently under investigation by the operator to determine if the recorded levels are correct, i.e. whether any abnormally elevated level may be due to the calibration/ performance of the instrument or site factors.

On this basis it can be concluded that the air quality in the Lake Macquarie - Wyong region was very good in June 2016.

How to read a windrose
Figure A-1: How to read a windrose

How to read a windrose
Wallsend - March 2013

Approximately 14% of total winds in March were from the south southwest.

Winds from the south-southwest that were within a speed range of 1.5-3m/s made up approximately 4% of the total winds in March.
